

# An alternative to coarse spaces? Piecewise Krylov Methods

Kévin Santugini

22nd International Conference on Domain Decomposition  
Methods

Lugano, September 16th–20th, 2013

- 1 Introduction
- 2 Rationales for Piecewise Krylov methods
  - First rationale: Coarse spaces algorithms behaviors
  - Second Rationale: generalization of Krylov methods
- 3 Piecewise Extrapolation and Krylov methods
  - Extrapolation Algorithms
  - Numerical Results
  - Possible improvements to Piecewise methods
- 4 Conclusion

# Importance of scalable algorithms

## Massive parallelism

Off the shelf clusters with more than 1000 cores are available.

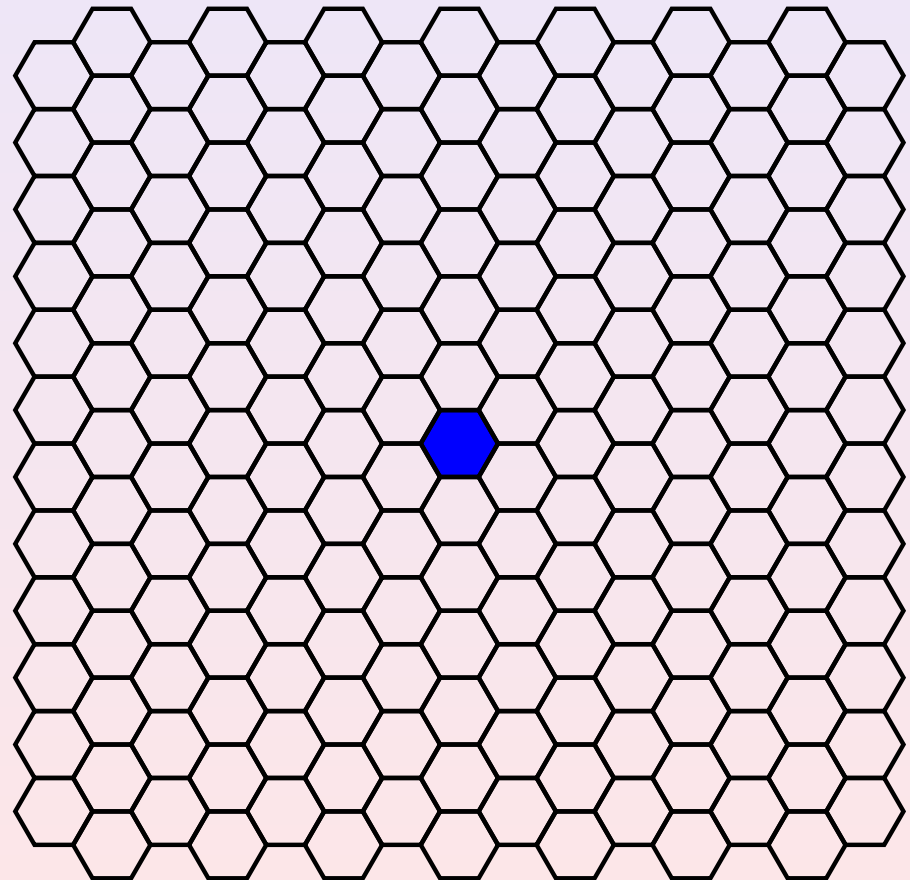

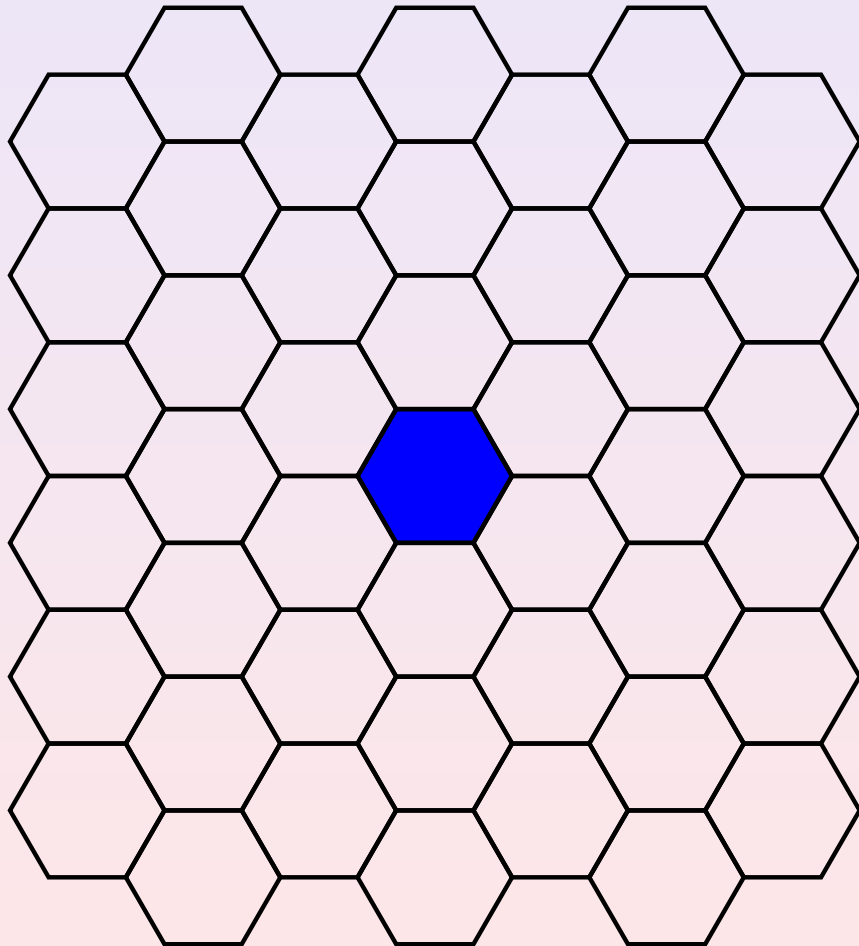

**Scalability is no longer optional.**

## Scalability

**Strong scalability:** For a given problem size, the computation time goes down as the number of computation units increase.

**Weak scalability:** More computation units allows to solve bigger problems in the same amount of time.

# Non Scalability of one-level DDM

# Non Scalability of one-level DDM

# Non Scalability of one-level DDM

# Non Scalability of one-level DDM

# The standard way of getting scalability: coarse spaces

Choose a coarse space  $X$

- 1 Either set  $u_i^0$  to 0 or to the coarse solution.
- 2 Until convergence
  - 1 Compute the uncorrected iterates  $u_i^{n+1/2}$  using Optimized Schwarz.

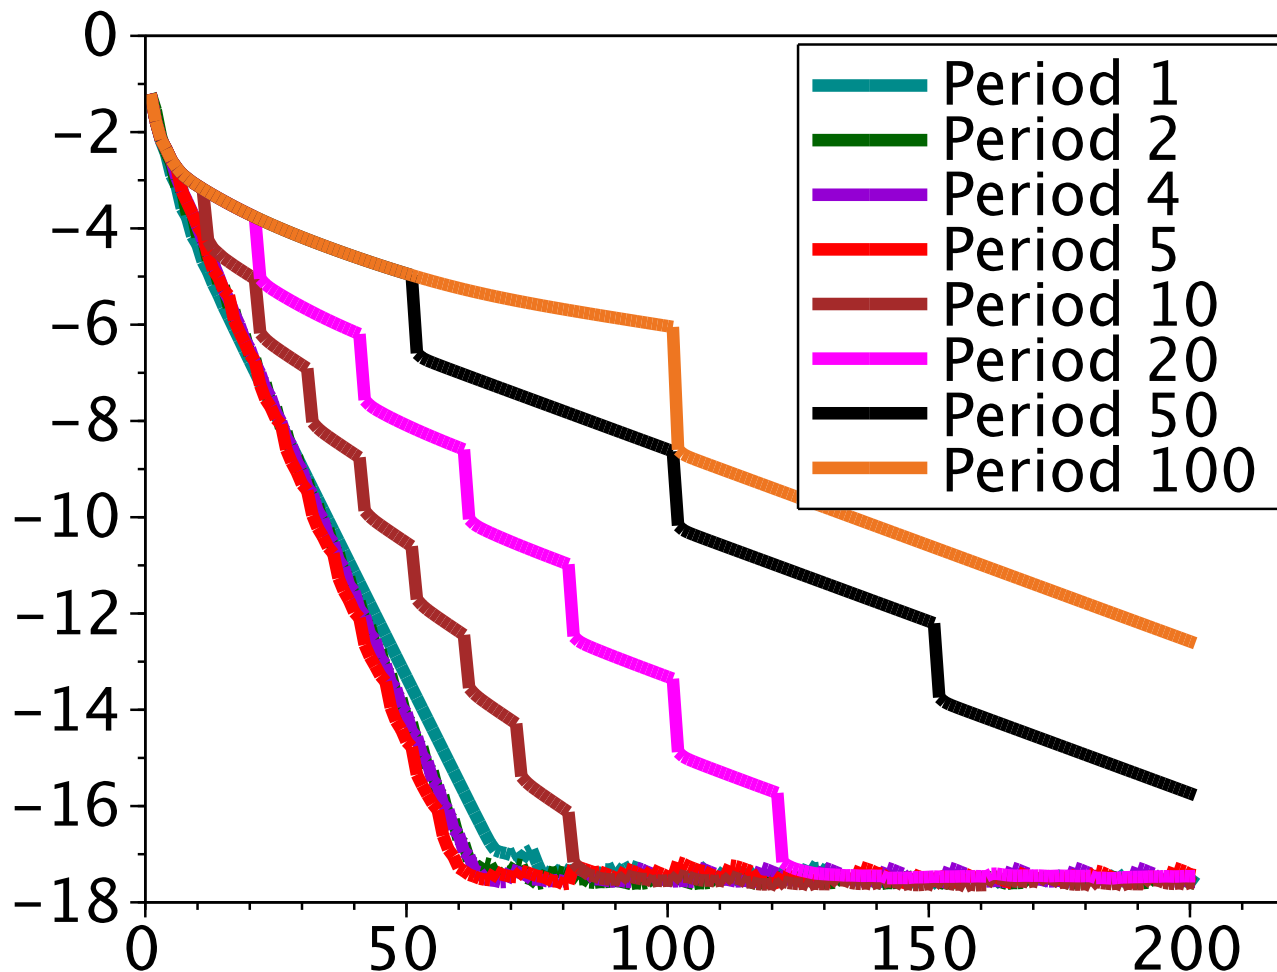

$$\begin{aligned}\mathcal{L}u_i^{n+1/2} &= f \quad \text{in } \Omega_i \\ \mathcal{B}_{ij}u_i^{n+1/2} &= \mathcal{B}_{ij}u_j^n \quad \text{on } \partial\Omega_i \cap \partial\Omega_j \\ u_i^{n+1/2} &= g \quad \text{on } \partial\Omega_i \cap \partial\Omega\end{aligned}$$

- 2 Compute in some way a coarse correction  $U^{n+1}$  in  $X$  defined over  $\Omega$ , then compute the corrected iterates

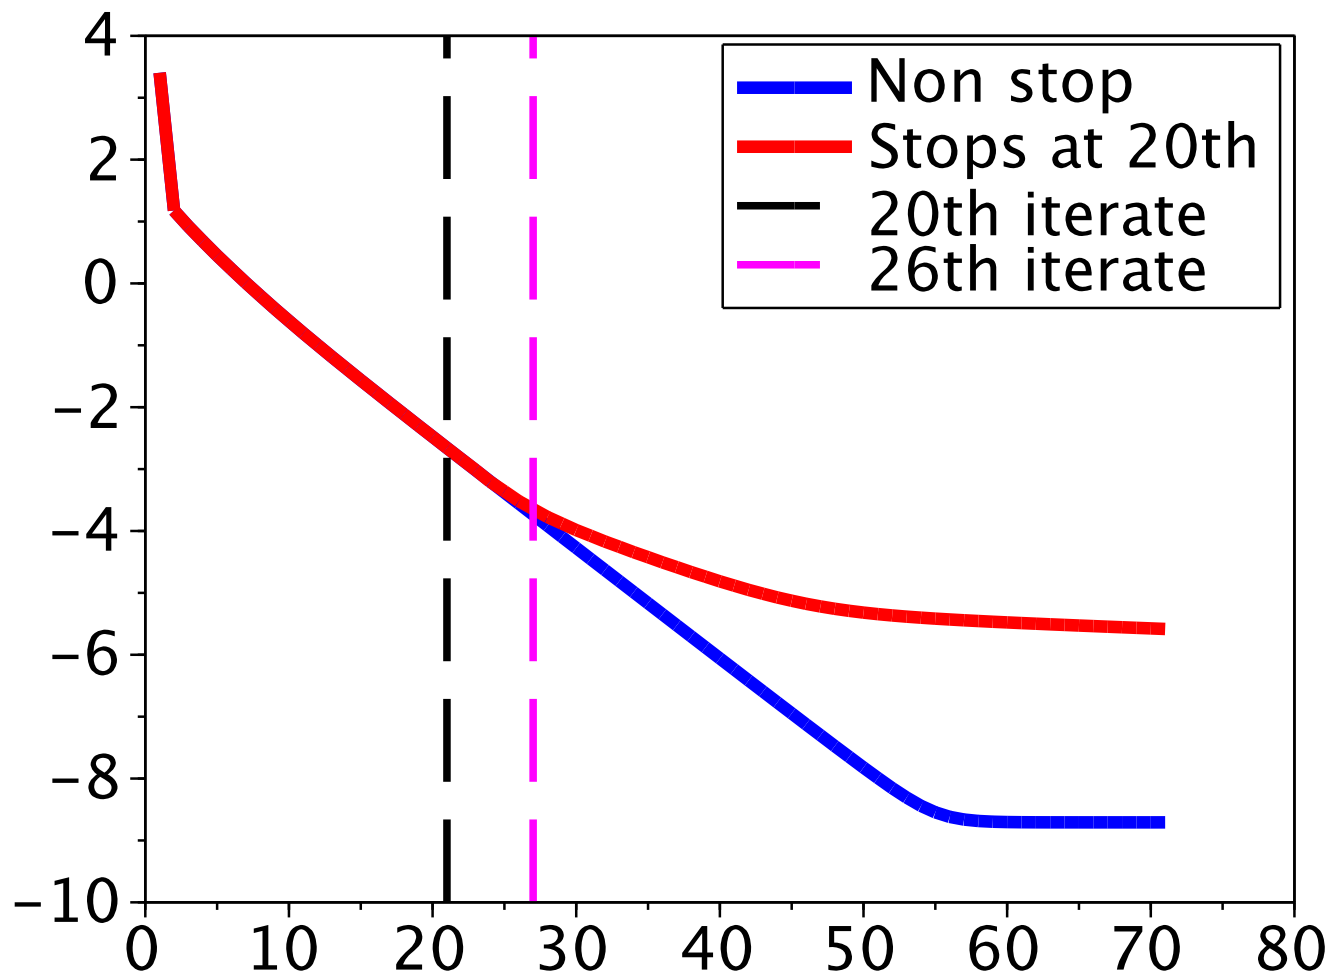

$$u_i^{n+1} := u_i^{n+1/2} + U^{n+1}|_{\Omega_i}$$

# Only applying the coarse correction every few iterates

# Stopping coarse correction after 20 iterates

# Changing the coarse space every iterate

## Observations

- 1 No need to apply coarse correction every iterate.
- 2 Using the same coarse space every iterate: always correcting the same errors.

## Coarse functions should

- 1 Satisfy the interior equation inside each subdomain.
- 2 Should be discontinuous.

## Cheap coarse spaces

If

$$\mathcal{L}(u^n) = f \quad \text{for all } n.$$

Then

$$\mathcal{L}(u^{n+1} - u^n) = 0 \quad \text{for all } n.$$

- 1 Use the successive  $u^{n+1} - u^n$  as coarse functions.
- 2 Or use

$$\begin{cases} u_i^{n+1} - u_i^n & \text{in } \Omega_i, \\ 0 & \text{in } \Omega_j \text{ when } j \neq i, \end{cases}$$

as coarse functions.

# Acceleration of Domain decomposition methods

Iterative methods are not used standalone in practice.

## Use of DDM as preconditioners

- Discrete/continuous linear differential operator  $\mathbf{A}_h$ .
- $\mathbf{A}_h$  is sparse. Its inverse is not.
- “Inverting” in parallel on each subdomain a restriction of  $\mathbf{A}_i$  to  $\Omega_i$ .
- Define the preconditioner as a combination of the inverse matrices computed in parallel and get the preconditioner  $\mathbf{P}$ .

Iterative method : Richardson on the preconditioned operator  $\mathbf{P}\mathbf{A}_h$ .

# Krylov methods as extrapolation methods

## Extrapolation methods

Find “best”  $\lambda_k^n$

$$u_{\mathcal{K}}^n = \sum_{k=0}^n \lambda_k^n u^k, \quad \sum_{k=0}^n \lambda_k^n = 1.$$

## Key properties

- 1 In **exact** arithmetic, Krylov methods equivalent to extrapolation methods.
- 2 In **floating point** arithmetic, Krylov methods are much more stable than extrapolation methods.
- 3  $u_{\mathcal{K}}^n$  satisfy the interior equation inside every subdomain

# Piecewise extrapolation

If  $\lambda_k^n$  depended on the subdomain then .

## Extrapolation methods

Find “best”  $\lambda_{i,k}^n$

$$u_{\mathcal{K}}^n = \sum_{i=0}^n \lambda_{i,k}^n u_i^k, \quad \sum_{k=0}^n \lambda_{i,k}^n = 1.$$

Per-subdomain  $\lambda$  parameters in extrapolation replaces coarse spaces for scalability. In practice too many parameters.

# Piecewise extrapolation with Robin jump minimizer

- 1 Set an initial guess.
- 2 Until convergence:
  - 1 Set  $u_i^{n+1/2}$  as the unique solution to

$$\begin{aligned} \eta u_i^{n+1/2} - \Delta u_i^{n+1/2} &= f \text{ in } \Omega_i, \\ \frac{\partial u_i^{n+1/2}}{\partial \mathbf{n}_i} + \rho u_i^{n+1/2} &= \frac{\partial u_j^n}{\partial \mathbf{n}_i} + \rho u_j^n \text{ on } \partial\Omega_i \cap \partial\Omega_j, \\ u_i^{n+1/2} &= 0 \text{ on } \partial\Omega_i \cap \partial\Omega. \end{aligned}$$

- 2 Set  $u_i^{n+1} := u_i^{n+1/2} + \sum_{k=0}^n \lambda_{i,k}^{n+1} (u_i^{k+1/2} - u_i^k)$  such that

$$\sum_{ij} \int_{\Gamma_{ij}} \left| \left( \frac{\partial u_i^{n+1}}{\partial \mathbf{n}_i} + q u_i^{n+1} \right) - \left( \frac{\partial u_j^{n+1}}{\partial \mathbf{n}_i} + q u_j^{n+1} \right) \right|^2$$

is minimized where  $q$  is another Robin parameter.

## Richardson with Piecewise line search algorithm

Use only a single direction per subdomain:  $u_i^{n+1/2} - u_i^n$ .

- 1 Set an initial guess.
- 2 Until convergence:
  - 1 Set  $u_i^{n+1/2}$  using Optimized Schwarz.
  - 2 Compute  $N$  scalars  $\lambda_i^{n+1}$  and set  $u_i^{n+1} := (1 - \lambda_i^{n+1})u_i^{n+1/2} + \lambda_i^{n+1}u_i^n$  such that

$$\sum_{ij} \int_{\Gamma_{ij}} \left| \left( \frac{\partial u_i^{n+1}}{\partial \mathbf{n}_i} + pu_i^{n+1} \right) - \left( \frac{\partial u_j^{n+1}}{\partial \mathbf{n}_i} + pu_j^{n+1} \right) \right|^2$$

is minimized.

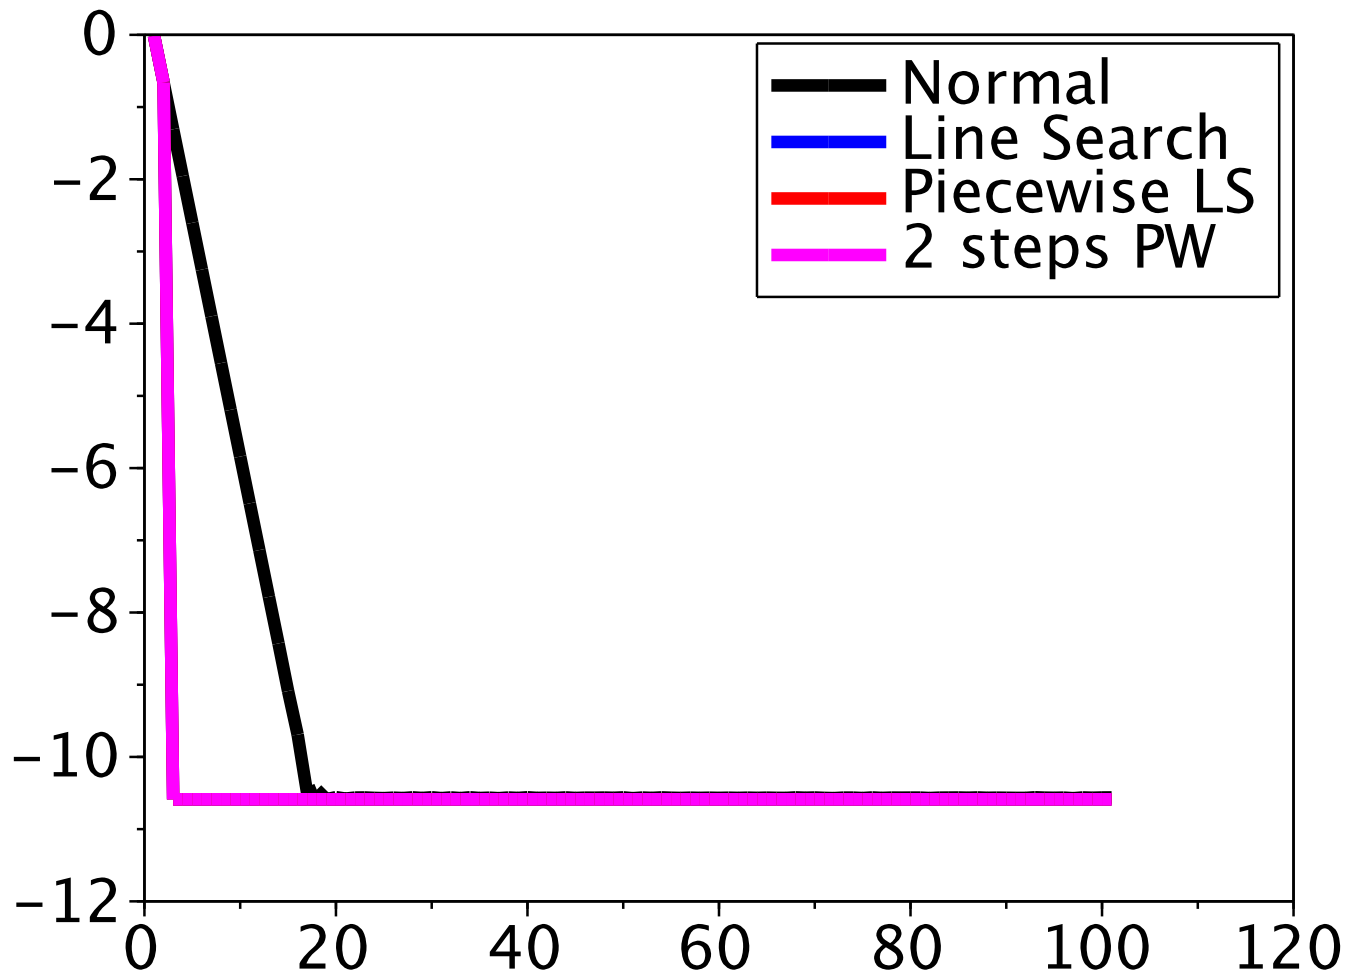

# Full Robin Minimizing Piecewise Extrapolation algorithm

Use only two directions per subdomain:  $u_i^{n+1/2} - u_i^n$  and  $u_i^{n-1/2} - u_i^{n-1}$ .

- 1 Set an initial guess.
- 2 Until convergence:
  - 1 Set  $u_i^{n+1/2}$  using optimized Schwarz
  - 2 Set  $u_i^{n+1} := u_i^{n+1/2} + \sum_i \lambda_i^{n+1} (u_i^{n+1/2} - u_i^n)$  so as to minimize

$$\sum_{ij} \int_{\Gamma_{ij}} \left| \left( \frac{\partial u_i^{n+1}}{\partial \mathbf{n}_i} + p u_i^{n+1} \right) - \left( \frac{\partial u_j^{n+1}}{\partial \mathbf{n}_j} + p u_j^{n+1} \right) \right|^2.$$

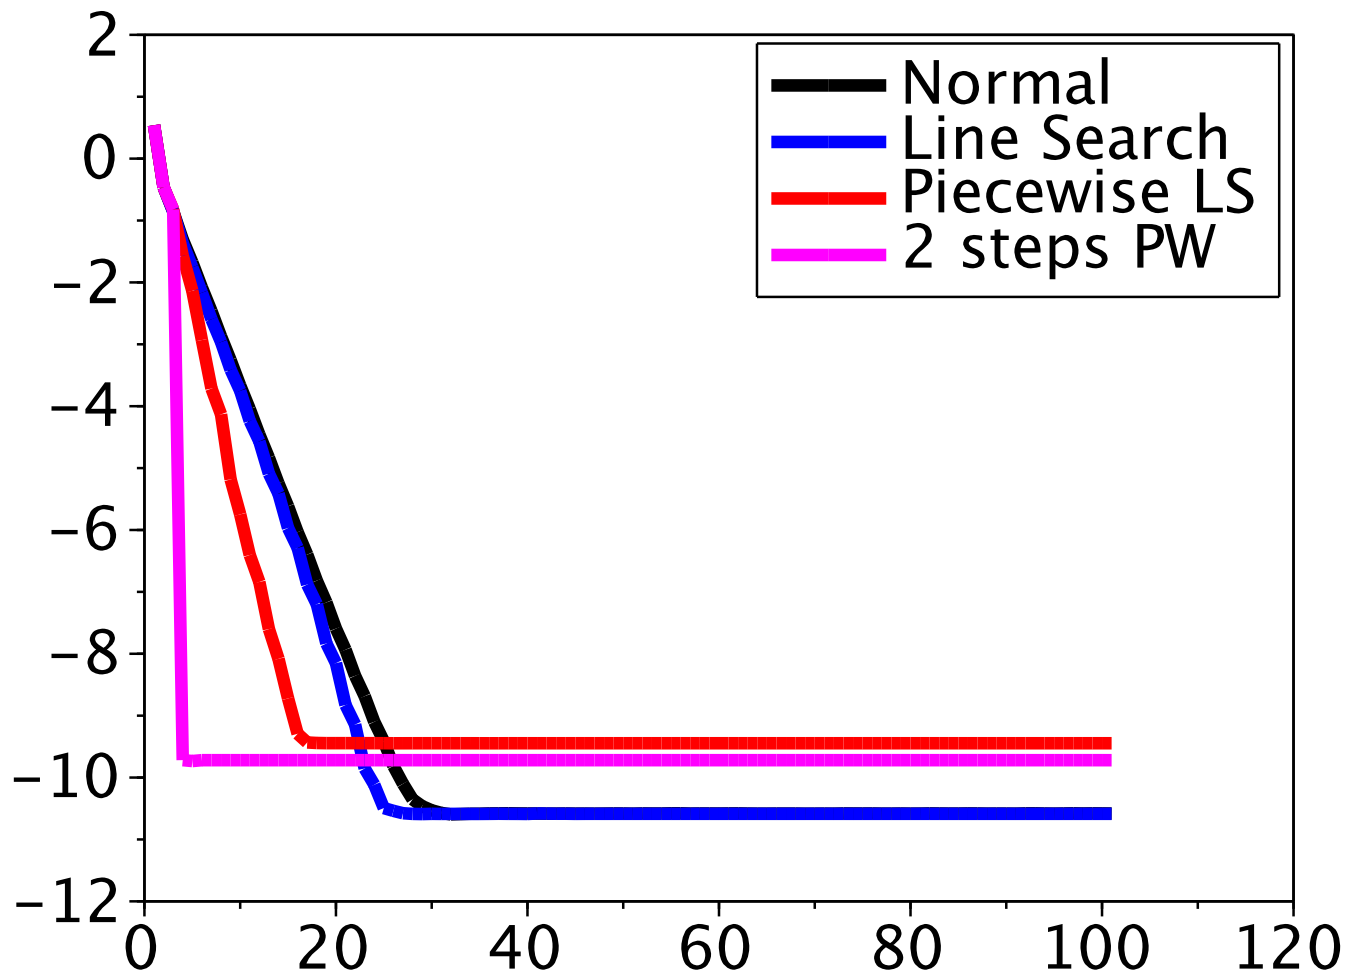

# Influence of numbers of subdomains: 2 subdomains in 1D

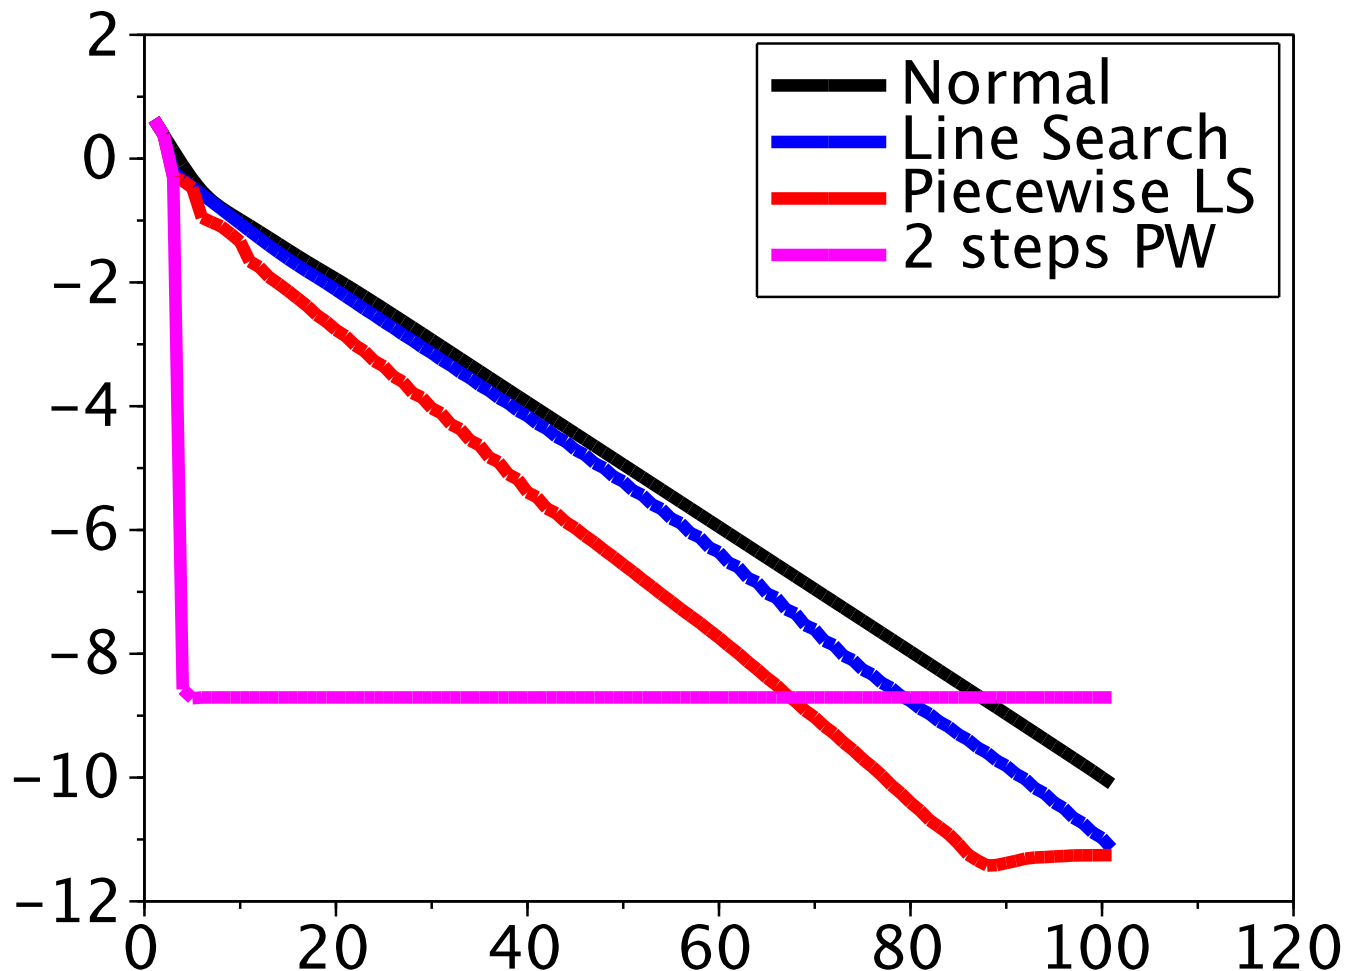

# Influence of numbers of subdomains: 5 subdomains in 1D

# Influence of numbers of subdomains: 10 subdomains in 1D

# Influence of numbers of subdomains: 40 subdomains in 1D

# Influence of numbers of subdomains: in $2D$

# Conclusion

- 1 Rationales for exploring Piecewise Krylov.
- 2 First numerical simulations in  $1d$  and  $2d$ .
- 3 Piecewise extrapolation works better than extrapolation on tested algorithms.
- 4 Piecewise extrapolation don't remove the need for a coarse space.

## Future works

- 1 Implementing Krylov instead of extrapolation (better numerical stability).
- 2 Elegant Piecewise GMRES using only piecewise Arnoldi coefficients?
- 3 Comparing fixed coarse spaces methods and piecewise Krylov.
- 4 Use both Discontinuous coarse spaces and piecewise Krylov.
